

portalpagos-26533 HTTP 500 burst

Impact time: 10/06/2026, 08:53 AM Severity: Sev1

Summary:

What happened

Between 13:35 and 14:15 UTC, the App Service **portalpagos-26533** returned sustained HTTP 500/503 failures on **/pagos.aspx**, triggering the Sev1 log alert tied to the workspace. The failures briefly cleared, then returned as a second burst before recovery after 14:12 UTC.

Analysis

- **Recent app changes preceded the outage.** Azure activity shows multiple `Microsoft.Web/sites` and `config/write` changes at 13:35–13:43 UTC, followed by restarts at 13:51 and 13:56 UTC.
- **The failing endpoint was concentrated and consistent.** `AppServiceHTTPLogs` recorded 3,258 HTTP 500s and 22 HTTP 503s, almost entirely on **/pagos.aspx**.
- **Failure onset was immediate.** The 5-minute bins show 100% failures at 13:48–13:50 UTC and again at 14:08–14:11 UTC.
- **A memory-pressure recycle happened later.** `AppServicePlatformLogs` reported `AutoHealingRecycle` at 14:11:50 UTC because the worker exceeded 90% memory. That aligns with fallout from the unstable app, not a separate upstream cause.
- **Metrics match the logs.** `Http5xx` spiked to 4,582 at 13:48 and 5,186 at 14:05; requests stayed high, so the app was failing under live traffic rather than sitting idle.
- **No Resource Health signal was available.** The subscription is not registered with `Microsoft.ResourceHealth`, so platform availability events could not be used here.
- **Free-text log analysis did not surface a separate anomaly.** The decisive signals were the HTTP logs, platform recycle, and change history.

What can be done next

1. **Revert or correct the recent portalpagos-26533 website/config changes** and confirm HTTP 500 rates return to baseline.
2. **Inspect the exact config/deployment diff from 13:35–13:43 UTC** to identify the setting or package that introduced the instability.
3. **Review memory growth and recycle behavior** to confirm whether the app needs a larger plan or a code fix to reduce memory pressure.
4. **Keep alerting on Http5xx and recycle/memory thresholds** so the next recurrence is detected earlier.
